Cataract and glaucoma are leading causes of blindness and visual impairment. Both conditions are age-related and thus they may co-exist. Cataracts may also cause glaucoma (phacomorphic glaucoma) and cataract may be accelerated as a result of glaucoma surgery. When cataract co-exists with glaucoma, cataract may be the trigger for seeking health care because the patient notices the coudy vision and white pupil caused by cataract, whereas the gradual visual loss due to glaucoma often occurs without the patient being aware of it until the glaucoma is in its advanced stages.

Glaucoma medication can increase the negative symptoms of cataract, such as miotics (e.g. pilocarpine), which can make the vision worse, and adrenergics, which can increase glare due to a degree of pupillary dilation.

In a patient with cataract, it is important to assess the optic nerve head to exclude glaucoma. If there is no view of the optic disc, other signs, such as relative afferent pupillary defect (RAPD) and raised intraocular pressure (IOP), may indicate co-existing glaucoma.

Cataract extraction, by whichever method, may be combined with any surgical glaucoma technique, including trabeculectomy, glaucoma drainage devices, minimally invasive glaucoma surgery (MIGS), and laser procedures such as endoscopic cyclophotocoagulation (ECP). Note: combined surgery is not recommended in patients with uveitic glaucoma (p. 82).

Performing glaucoma surgery alone may accelerate the cataract, which means the patient will need a cataract operation soon. Performing cataract surgery alone may lower the intraocular pressure (IOP) independently, but this is inconsistent, especially in poorly controlled glaucoma with severe visual field loss. There is inconclusive evidence of an increased risk of complications in combined surgery over cataract surgery alone, and information about long-term outcomes (follow-up of five years or more) is not available. Whether cataract surgery is done after trabeculectomy surgery (at least six months after) or combined with trabeculectomy surgery, the pre-operative assessment should include counselling to help patients understand that the visual outcome of their operation will depend on the degree of optic nerve damage they have. Keep their expectations modest. Inform patients about the possibility of bleb failure and that glaucoma medications may still be required postoperatively, in the long term.

Cataract surgery for patients who have had previous trabeculectomy

This is regarded as complicated cataract surgery, requiring thorough preoperative examination and preparation, a surgical plan and proactive postoperative care.

Note the following:
- Visual symptoms (e.g., glare, haloes around lights), visual acuity, and the possible causes of reduced vision (due to the contribution of the cataract and/or the progression of glaucoma).
- The severity of the glaucoma. Estimate optic disc cupping, which is visible if the lens opacity is not dense. The current IOP will determine target IOP and predict the need for another glaucoma intervention.
- The number and frequency of glaucoma medications currently used to control IOP. This may indicate whether the bleb is fully functioning or not.
- The number and type(s) of previous surgery and the presence of any drainage device. For recent trabeculectomy or implant, it is advised to delay cataract surgery until the bleb matures (at about six months).
- The bleb position will determine the approach for the cataract surgery incision, which should avoid the bleb area. Note whether the bleb is functioning, and whether it is cystic or flat and/or fibrosed or vascularised. This will determine whether intraoperative bleb revision is required.
Combined cataract and glaucoma surgery may be the procedure of choice if the skill of the surgeon is adequate, the patient understands the procedure and expected outcomes, procedure of choice if the skill of the surgeon is adequate, the patient understands the procedure and expected outcomes, which may increase the risk of postoperative inflammation, which may compromise bleb function.

Pseudoxfoliation, as this may be associated with weak zonules, which is a reason for caution in cataract surgery.

Previous surgery, which may also cause weak zonules and vitreous disturbance, as well as corneal endothelial cell loss, which poses a greater risk of postoperative corneal oedema and decompensation.

Intraoperatively, use extra caution and pay attention to the following:

- **Care of the existing bleb**, especially if thin and cystic, during placement of the lid speculum and any physical manipulation or instrumentation of the eye during wound incision and paracentesis.
- **Bleb revision**, if needed. This can be done using needling and/or additional application of antimetabolites.
- **Maintaining the anterior chamber (AC) depth**, especially in patients with a high functioning bleb. Take extra caution to prevent posterior capsular rent and vitreous loss. Ensure that any tube that is in place is not blocked, obstructed or displaced.
- **Review a functioning tube**, if present. It can be repositioned or flushed to improve the chances of it functioning after surgery. It may also be trimmed if too long.
- **IOL placement.** The aim is to place the IOL in the bag; otherwise, be prepared for a sulcus placement if the capsule or zonules are compromised. Position the lens so that the haptic is away from the primary incision (to avoid it migrating into the AC). Avoid AC IOLs because they can directly affect the bleb and may produce undue postoperative inflammation.
- **AC washout.** Thoroughly remove viscoelastic as well as nuclear and cortical lens material. This will prevent blockage of drainage channels and/or tubes and reduce postoperative inflammation and IOP spikes. However, take care to prevent excessive flushing against the corneal endothelium as this can cause damage.
- **Wound closure.** Use sutures to produce a watertight wound. A wound leak will increase the risk of bleb failure.

Proactive postoperative care involves regular visits and long-term follow-up to assess IOP, visual fields, and bleb morphology and function.

- **Watch out for bleb failure**—examine for bleb leak and aqueous misdirection. Actively check for retained lens fragments or iris incarceration in the sclerectomy site that may cause blockage.
- **Aggressively treat postoperative inflammation to prevent fibrosis.** At the end of surgery, give an extra subconjunctival corticosteroid injection (e.g. 4 mg dexamethasone). Avoid miotics and prostaglandins and use more postoperative steroid eye drops (e.g. dexamethasone hourly) and non-steroidal anti-inflammatory eye drops (e.g. diclofenac).
- **Measure the IOP regularly and treat IOP spikes** with appropriate glaucoma medications.

**A Preparing the scleral area for trabeculectomy**

1. Use peribulbar anaesthesia or a retrobulbar block.
2. Clean the periorcular area with 5% povidone iodine for 3 minutes.
3. Insert a superior rectus traction suture with 6-0 silk, taking care not to damage the conjunctiva.
4. Dissect a fornix-based conjunctival flap superiorly and or zonules are compromised. Position the lens so that the haptic is away from the primary incision (to avoid it migrating into the AC). Avoid AC IOLs because they can directly affect the bleb and may produce undue postoperative inflammation.

**Combined surgery when:**

- The position of the peripheral iridectomy and the pupil’s ability to dilate. Iris manipulation during cataract surgery with floppy iris or poor dilation due to posterior synchia may increase the risk of postoperative inflammation, which may compromise bleb function.

**Combined cataract and glaucoma surgery**
**B Performing the MSICS**

1. At about 3 mm posterior to the corneal limbus, use a crescent blade to make a partial thickness scleral tunnel of 5–7 mm in width.
2. Continue the dissection for 1–2 mm into the clear cornea with the scleral pockets continued in the same plane. Leave the sides of the scleral tunnel intact.
3. Make a temporal corneal paracentesis and inject viscoelastic.
4. Perform a capsulorrhexis of about 5–6 mm through the side port.
5. From the scleral tunnel position, enter the anterior chamber with a 3.2 mm keratome at 12 o’clock to enlarge the inner lip to 8–9 mm wide.
6. Using hydrodissection, rotate and prolapse the lens nucleus into the anterior chamber using a Sinskey hook.
7. Deliver the nucleus with an irrigating vectis or with the inner scleral flap.
8. Make a temporal corneal paracentesis and inject viscoelastic.

**D Postoperative care**

Postoperatively, patients are treated with antibiotic eye drops (e.g. ciprofloxacin 0.3%) four times a day, corticosteroid eye drops (e.g., dexamethasone 0.1% or prednisolone acetate 1%) six times a day for one week and tapered over two months. Cyclopregics may be used to reduce discomfort. The use of anti-glaucoma medication will depend on the IOP.

The preferred postoperative examination schedule is at postop Day 1, Day 3, at one week, at one month, at 3 months and thereafter scheduled at reasonable intervals, as required. At each visit, the best corrected visual acuity, IOP and complications, if any, are noted. In addition to applying the basics of good postoperative care after glaucoma surgery, be alert for the symptoms and signs of complications of cataract surgery.
